

## CHAPTER 11

### The Neo-Keynesian Model

Sasan Fayazmanesh

#### Summary

This chapter deals with the Keynesian (neo-Keynesian) model of the equilibrium output.

It covers: 1) the consumption function, including marginal propensity to consume; 2) saving function, including marginal propensity to save; 3) investment function; 4) government expenditure function; 4) aggregate expenditure function; and 5) equilibrium level of output.

It also covers the concept of Keynesian or “expenditure multiplier.”

#### Introduction to neo-Keynesian Economics

Neoclassicals’ laissez faire theories of the labor market and loanable funds market made no sense during the Great Depression of 1929-1939.

The theories and pictures did not match!

- Wages fell, but there was no increase in employment
- Interest rates fell, but there was no new investment
- Supply did not create its own demand

“Work is what I want, not charity. Who will help me get a job? 7 years in Detroit, no money, sent away. Furnish best of references, phone . . .”

In *The General Theory of Employment, Interest and Money* (1936), Keynes challenged some aspects of these theories, as well as the Say's Law.

See: [General Theory](#)

Keynes went on to develop a new theory of:

- 1) How **output** and **employment** are determined.
- 2) How **interest rate** is determined.
- 3) What is the role of **money** in the economy.

Soon after, however, Keynes's ideas were simplified and incorporated into the neoclassical models.

This was the beginning of the “**neoclassical synthesis**” or “**neo-Keynesian**” model.

**The Basic Neo-Keynesian Model**

We start with the GNP (Y) identity:

$$Y = C + I_g + G + (X - M)$$

### Simplifying assumptions

1) Economy is "closed": No  $X - M$

$$Y = C + I_g + G$$

2) Economy is "private": No  $G$

$$Y = C + I_g$$

3) There is no depreciation:

Gross investment = Net investment

$$Y = C + I$$

These assumption also make **output** (GNP) and **income** (disposable personal income) **equal**:

$$NNI = Y - \text{Depreciation} - \text{IBTs}$$

$$PI = NNI + \text{Transfer payments}$$

$$DPI = PI - \text{Direct taxes}$$

These assumption also make **output** (GNP) and **disposable personal income equal**:

$$NNI = Y - \text{Depreciation} - \text{IBTs}$$

$$PI = NNI + \text{Transfer payments}$$

$$DPI = PI - \text{Direct taxes}$$

$$Y = \text{DPI}$$

Since

$$Y = \text{DPI} = \text{Consumption} + \text{Savings}$$

Then :

$$1) Y = C + S$$

$$2) Y = C + I$$

1 and 2 imply:

$$3) S = I$$

Since  $C + S = C + I$

Note:  $S = I$  is just an accounting identity.

As we will see,  $S = I$  does not imply economic stability, since  $I$  is actual investment ( $I_a$ ) as opposed to planned investment ( $I_p$ ):

$$I_a = I_p + \Delta \text{Inventories}$$

Stable economy implies:

$$\Delta \text{Inventories} = 0 \text{ and}$$

$$S = I_p$$

### Consumption Function

Keynes hypothesized that consumption spending is a function of disposable personal income:

$$C = f(Y).$$

This idea became known as the consumption function:

Def. **Consumption function (C)**: a relationship between **consumption spending** and income (disposable personal income).

After Keynes, it was argued that consumption depends on various other factors:

$$C = f(Y, W, i, E)$$

Where,

**W:** is wealth or assets,

**i:** is interest rate,

**E:** is expectation of future income.

**Keynes assumed:**

- 1) There is a **minimum amount of consumption**; i.e., even when national income is zero, there is still some consumption. This is called autonomous consumption.

Q: Where could this consumption come from?

A: Past savings.

- 2) **Consumption rises as national income rises**, but it does **not rise as fast**.

**Consumption function**

**Shifts or Changes in Consumption**

If

$$C = f(Y, W, i, E),$$

then any change in  $W, i,$  or  $E$  will shift the consumption function.

Example,

What happens if **interest rates fall**?

**Interest rates falls**

**Linear consumption function:**

We assume that consumption function is given by :

$$C = a + bY$$

Where “**a**” is the C intercept and “**b**” is the **slope of the consumption function**.

It must be that:

$$0 < b < 1$$

### Marginal Propensity to Consume

Def. Marginal Propensity to Consume (MPC) : The increase in consumption which results from an increase in income:

$$MPC = \Delta C / \Delta Y$$

This is obviously the same as the slope of the consumption function or “b”:

$$MPC = b$$

### Example

$$MPC = \Delta C / \Delta Y$$

$$MPC = (C_2 - C_1) / (Y_2 - Y_1)$$

$$MPC = (\$1000 - \$850) / (\$1200 - \$1000)$$

$$MPC = \$150 / \$200$$

$$MPC = 3/4 = .75$$

### Average Propensity to Consume

Def. Average Propensity to Consume (APC) :

The level of consumption divided by the level of income:

$$APC = C / Y$$

APC obviously changes as income changes.

### Example

$$APC_1 = C_1 / Y_1$$

$$APC_1 = \$850 / \$1000$$

$$APC_1 = .85$$

$$APC_2 = C_2 / Y_2$$

$$APC_2 = \$1000 / \$1200$$

$$APC_2 = .83333$$

### Saving Function

$Y = S + C$ , Therefore,

$$S = Y - C$$

If  $C = a + bY$ , then

$$S = Y - (a + bY)$$

$$S = Y - a - bY$$

$$S = -a + (1 - b)Y$$

### Saving function

### Marginal Propensity to Save

Def. Marginal Propensity to Save (MPS) : The increase in saving which results from an increase in income:

$$MPS = \Delta S / \Delta Y$$

This is the same as the slope of the savings function or "1-b"

$$MPS = 1 - b$$

### Example

$$MPS = \Delta S / \Delta Y$$

$$MPS = (S_2 - S_1) / (Y_2 - Y_1)$$

$$MPS = (\$200 - \$150) / (\$1200 - \$1000)$$

$$MPS = \$50 / \$200$$

$$MPS = 1/4 = .25$$

**Q:** What do we get when we add MPC and MPS?

**A:** One!

Our example:

$$MPC = .75$$

$$MPS = .25$$

$$MPC + MPS = .75 + .25 = 1$$

MPC + MPS = 1 is true by definition:

$$MPC = b$$

$$MPS = 1 - b$$

$$MPC + MPS = b + 1 - b = 1$$

Similarly

$$Y = C + S$$

$$\Delta Y = \Delta C + \Delta S$$

Divide both sides by  $\Delta Y$

$$\Delta Y / \Delta Y = \Delta C / \Delta Y + \Delta S / \Delta Y$$

$$1 = MPC + MPS$$

**Q: What do we get when we add APC and APS?**

**A: One, again!**

Our example:

$$APC = .85$$

$$APS = .15$$

$$APC + APS = .85 + .15 = 1$$

APC + APS = 1 is also true by definition:

$$Y = C + S$$

Divide both sides by Y:

$$Y/Y = C/Y + S/Y$$

$$1 = APC + APS$$

### Investment Function

Remember that **actual investment (I)** has 3 components:

- 1) Structures and equipment
- 2) Residential structures
- 3) Changes in inventories

Also remember the relation between actual investment ( $I_a$ ) and planned investment ( $I_p$ ):

$$I_a = I_p + \Delta \text{Inventories}$$

Def. **Planned investment ( $I_p$ )** is what firms wish or plan to invest.

Keynes assumed that **planned investment**:

- 1) Is independent of the level of national income.
- 2) Depends on **interest rate**, as we shall see later.

**Planned investment function**

**Equilibrium Level of GNP (Y)**

Q: At what level of consumption, saving and investment will the GNP be in equilibrium, i.e., it is neither expanding nor contracting?

A: We can answer this question in 2 ways:

- 1) By looking at the relationship between savings and investment, or
- 2) By looking at the relation between expenditures (C and I) and national income.

**Savings and Investment: Equilibrium level of GNP**

**Savings and Investment: Equilibrium level of GNP**

**Savings and Investment: Equilibrium level of GDP**

### Aggregate Expenditure

We can also look at the level of equilibrium GDP by looking at where **aggregate expenditure** is equal to income.

Def. **Aggregate Expenditure (AE)**: Is the sum of the spending. So far we have:

$$AE = C + I$$

### Aggregate Expenditure

### Aggregate Expenditure

### The 45° line

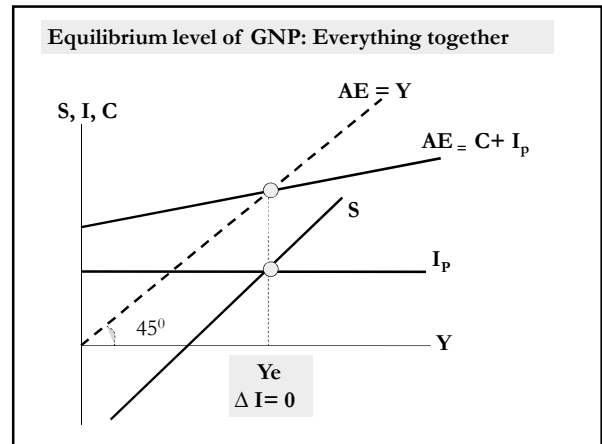

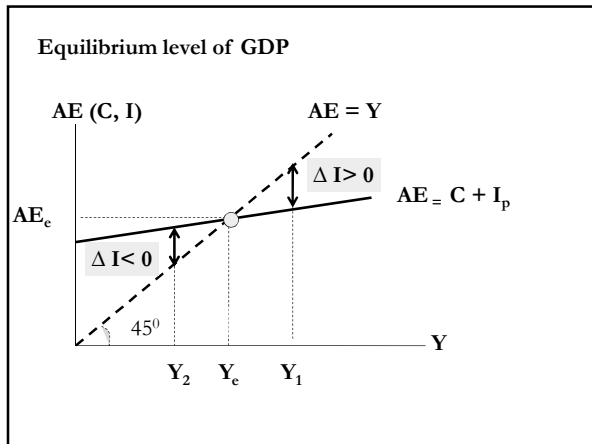

### Equilibrium level of GDP

Note: At equilibrium level of output,  $Y_e$ , all income is spent.

Economy is neither expanding nor contracting.

It is stable and  $\Delta I = 0$ .

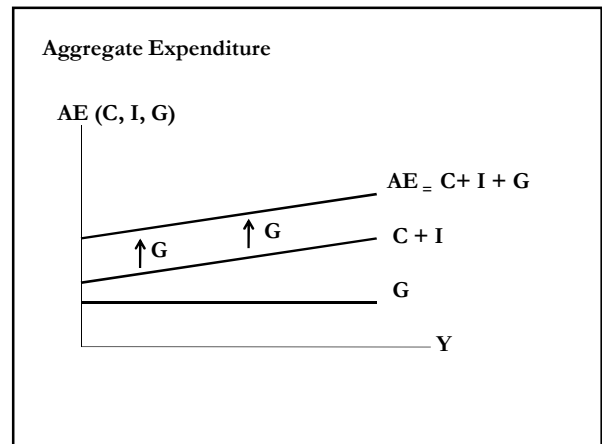

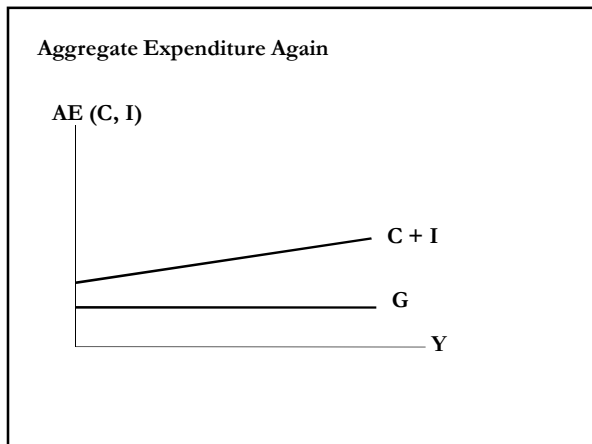

### Government expenditure

Suppose the equilibrium level of output is achieved at a low level of employment.

Keynesian economics then advocates government spending money on goods and services.

We assume that government expenditure,  $G$ , is independent of national income:

**The Multiplier Effect**

Def. **Multiplier Effect**: Any change in spending will bring about greater change in income or output:

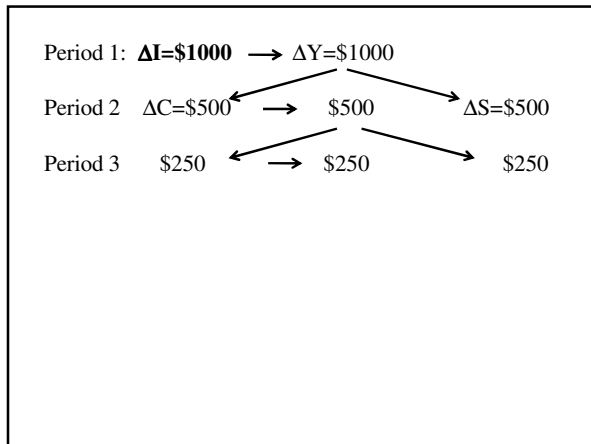

$\Delta Y > \Delta AE$

**A Numerical Example**

Suppose  $MPC=1/2$  and investment increases by **\$1000**, i.e.,  $\Delta I = \$1000$ .

What happens to the national income?

Remember the geometric series:

$$S = a + ar + ar^2 + ar^3 + ar^4 + \dots$$

Where

$$0 < r < 1$$

The series converges:

$$S = a / (1 - r)$$

**Net Result:**

$$\Delta Y = \$1000 + \$500 + \$250 + \$125 + \$62.5 + \dots$$

$$\Delta Y = \$1000 + \$1000 (1/2) + \$1000 (1/2)^2 + \dots$$

$$\Delta Y = \$1000 / (1 - 1/2) = \$1000 / (1/2) = 2 \times \$1000$$

**$\Delta Y = \$2,000$**

**Algebraic method of calculating multiplier**

$$\Delta Y = \Delta AE / (1 - MPC) = \Delta AE / (MPS)$$

We call  $k = \frac{1}{1 - MPC} = \frac{1}{MPS}$

**the multiplier factor**, Keynesian or expenditure multiplier.

Proof (not required)

- 1)  $Y = C + I$
- 2)  $\Delta Y = \Delta C + \Delta I$
- 3)  $\Delta Y - \Delta C = \Delta I$  (divide both sides by  $\Delta Y$ )
- 4)  $(\Delta Y - \Delta C) / \Delta Y = \Delta I / \Delta Y$
- 5)  $1 - MPC = \Delta I / \Delta Y$
- 6)  $\Delta Y = \Delta I / (1 - MPC)$

Our previous example :

Investment increased by \$1000 and MPC= 1/2.  
By how much will national income rise?

$$\Delta Y = \Delta AE / (1 - MPC)$$

$$\Delta Y = \Delta I / (1 - MPC)$$

$$\Delta Y = \$1000 / (1 - 1/2)$$

$$\Delta Y = \$1000 / (1/2)$$

$$\Delta Y = \$2000$$

Another example of multiplier:

Suppose government expenditure, G, falls by \$150 and MPC = 2/3. By how much will national income fall?

$$\Delta Y = \Delta AE / (1 - MPC)$$

$$\Delta Y = \Delta G / (1 - MPC)$$

$$\Delta Y = - \$150 / (1 - 2/3)$$

$$\Delta Y = - \$150 / (1/3)$$

$$\Delta Y = - \$450$$

#### Does the multiplier work in reality?

Some Keynesians argue that “**automatic stabilizers**” might hinder the effectiveness of multiplier.

Def. **Automatic stabilizers** are economics forces that try to stabilize economy automatically.

#### Examples of automatic stabilizers

- **Progressive income tax:** as income goes up, people fall in higher marginal tax rate.
- **Prices:** as economy expands, inflation rises, reducing spending.
- **Interest rate:** also, as economy expands, interest rates rise, slowing expenditures.

Next stop: Chapter 11.
