Challenges from first LHC Data

Statistical fluctuation or first sign of New Physics?

Outline

- Review/problem of current LHC search methods & significance calculation
- General procedures for searching new physics with an unknown location or shape
- A New Method vs Sliding Window
- Results and Conclusion
- Significance of $H \rightarrow \gamma\gamma$ (ATL-COM-PHYS-2006-009 by I. Koletsou, G. Unal, etc)
- Photon Conversion & $H \rightarrow \gamma\gamma$ (David Joffe)

Search for Signal in HEP

Strategy: Search for excess of events in a certain region of a kinematic observable

Observation Probability: $P(n,B) = e^{-B} B^n/n!$

- Gaussian Statistics if B is large ($B > 25$)
- Observation significance: S/\sqrt{B} where $S=n-B$

HEP definition of observation significance:

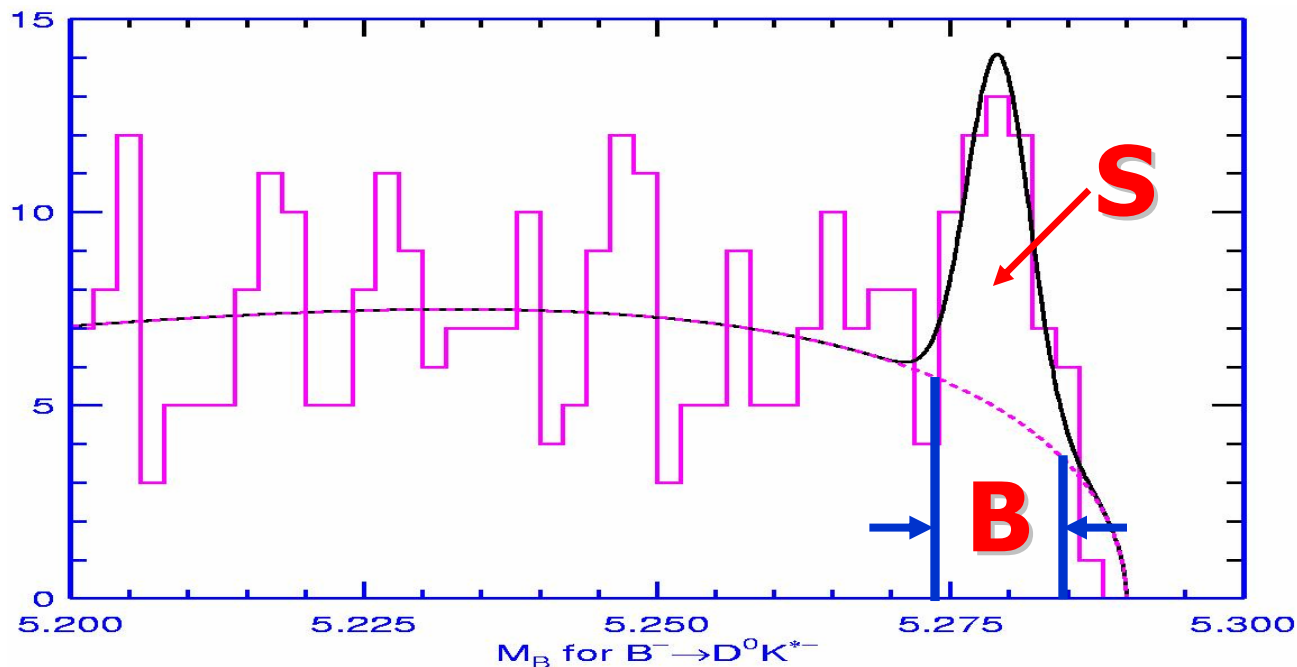

| Definition | 1σ | 2σ | 3σ | 4σ | 5σ |
|------------------------------------|-----------|-----------|-----------|-----------|----------------------|
| Observation due to BKG fluctuation | 15.87% | 2.28% | 0.14% | 0.0032% | 2.9×10^{-7} |

Signal with **known shape/location**

To maximize observation significance S/\sqrt{B} :

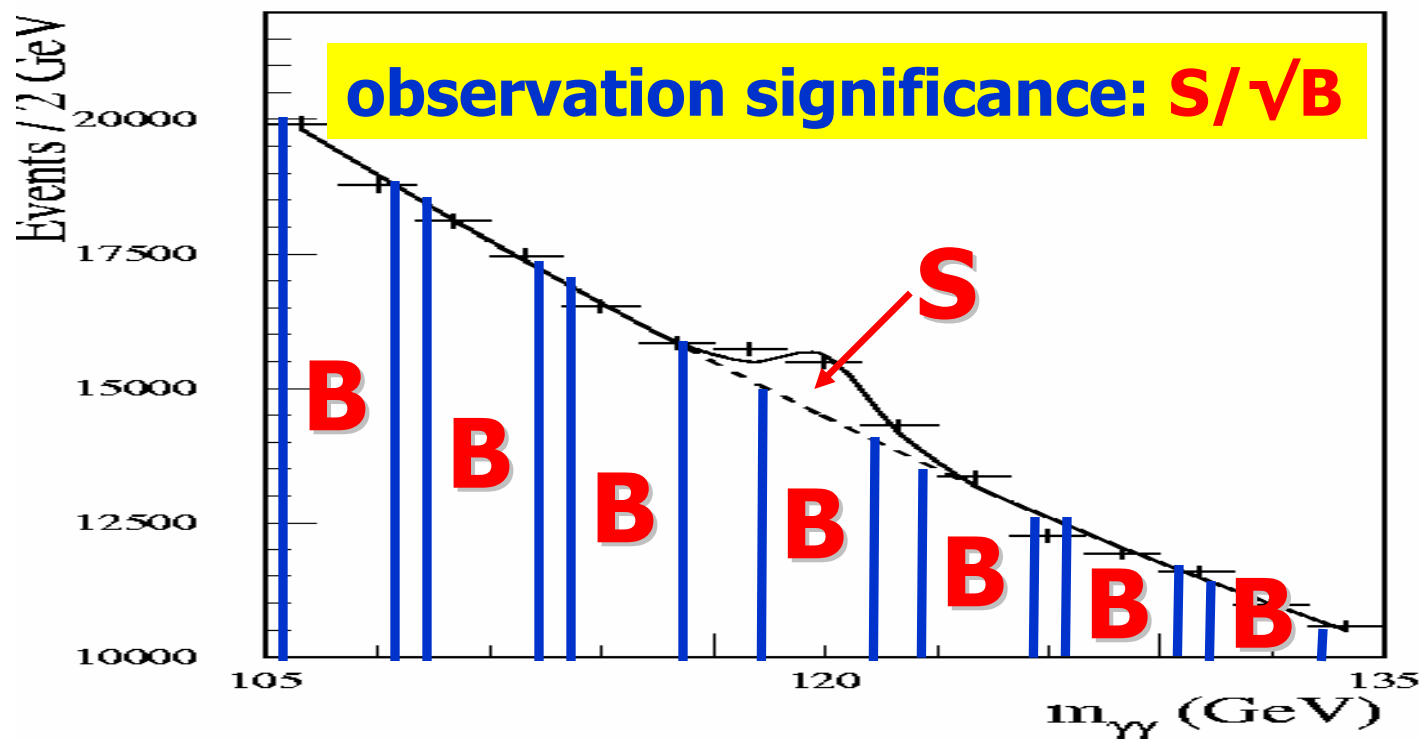

- Search region: $\pm 2\sigma$ around known Gaussian mean
- Exclude where signal has little chance to show up
- Only valid when BOTH shape/location are known

Current LHC Search Method

- New Particle's Mass: Unknown! Range: TeV
- Use "Sliding-Window" and search for excesses
- Significance: Calculated for each sliding window

Current LHC Significance Calculation

- Each significance (S/\sqrt{B}) based on a $\sim 2\sigma$ window

Signal with **unknown location**

- Explore kinematic region from 0 to 100
- **Background:** **Flat** distribution from 0 to 100
- **Possible Gaussian Signal:** Stand. Deriv. $\sigma = 1$
Unknown mean from 2 to 98
- “Sliding-Window”: **Width=4** and move center from 2 to 98 with **step size of 16,8,4,2,1,0.5,0.2,0.1**
- MC experiment: 500 **background-only** events
- Check how often we find **“significant”** (**S/\sqrt{B}**) signals from any **background-only** MC exp.

Problem with LHC Search Method

Based on **13,400,000** MC experiments

Each experiment contains 500 **background-only** evts

| Step-Size | $S/\sqrt{B}>1$ | $S/\sqrt{B}>2$ | $S/\sqrt{B}>3$ | $S/\sqrt{B}>4$ | $S/\sqrt{B}>5$ |
|-------------------|-------------------------------------|-------------------------------------|-------------------------------------|-------------------------------------|----------------------------------------|
| 16 | 70.89% | 20.42% | 1.52% | 0.11% | 0.002% |
| 8 | 91.56% | 35.25% | 2.82% | 0.20% | 0.003% |
| 4 | 99.72% | 58.53% | 5.38% | 0.39% | 0.007% |
| 2 | 99.99% | 77.86% | 9.64% | 0.73% | 0.015% |
| 1 | 100.0% | 89.03% | 14.86% | 1.24% | 0.027% |
| 0.5 | 100.0% | 94.33% | 19.97% | 1.83% | 0.042% |
| 0.2 | 100.0% | 97.17% | 25.42% | 2.56% | 0.064% |
| 0.1 | 100.0% | 98.01% | 28.21% | 2.98% | 0.078% |
| Definition | 15.87% | 2.28% | 0.14% | 0.003% | 2.9×10^{-7} |

Problem with LHC Search Method

- “Significance” over-estimated
- Multiple tests over **many sub-samples**, but significance is calculated according to **only one sub-sample** (False-Positive problem due to multiple-testing)
- “Significance” depends on specifics of the the search method (i.e. Step Size) and the situation it applies to.

Any Search Method

Type I error rate

- Measures how often false signals are claimed when there are only backgrounds
- "Significance" definition in HEP

Power/Sensitivity

- Measures how often real signals can be correctly identified when they present

General Procedures

New physics with unknown location/shape:

Re-evaluate significance for each method so it follows HEP significance definition using

“Background-only experiments”

Power/Sensitivity to be determined by

“Signal-Embedded experiments”

Compare **sensitivity** for different methods

Sensitivity depends on signal location:

- Vary signal location (**Best/Worst scenario**)
- Vary amount of signal embedded

A New Analysis Method

- Apply Maximum Likelihood to **entire** sample
- Find **best fit** to the **entire** sample
(scan available parameter space)

Re-evaluate significance first (same for SW), so they follows HEP significance definition using **“Background-only experiments”**

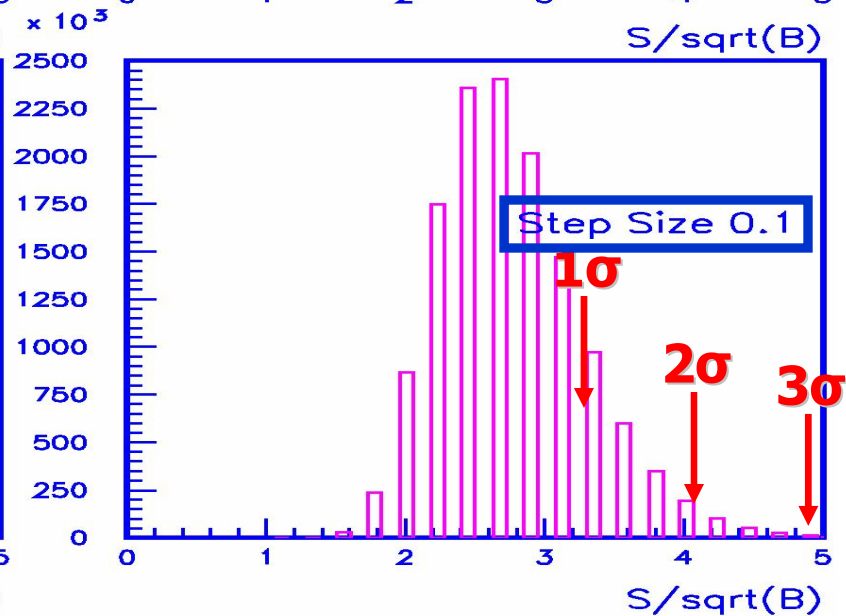

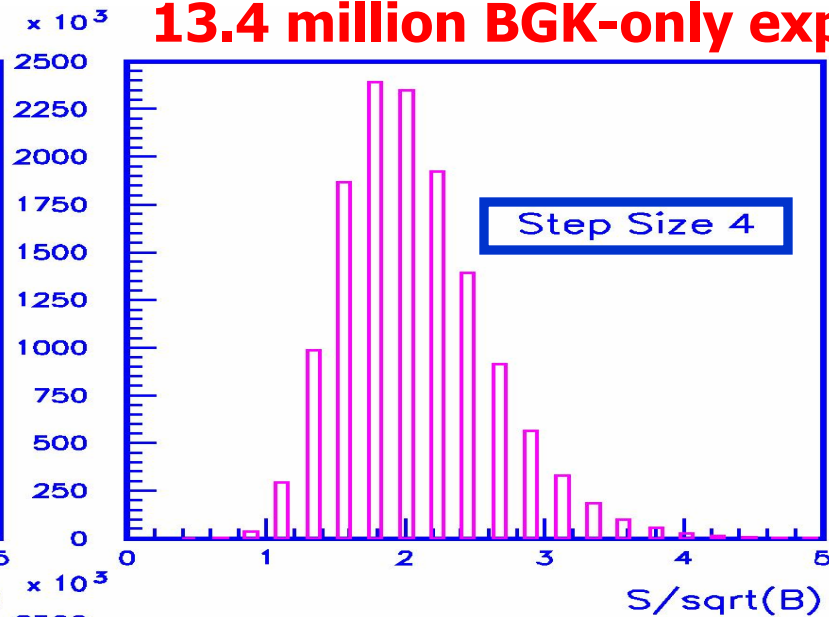

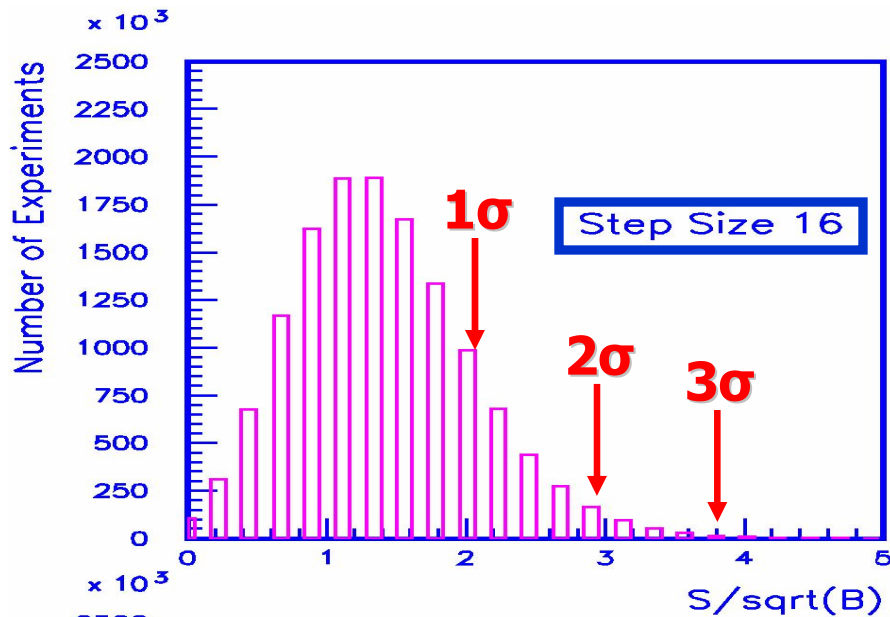

Comparing sensitivities of SW and NM

How often signals are found **correctly** with a certain significance (rescaled with “BKG-only”)

SW significance recalculation

13.4 million BGK-only expts

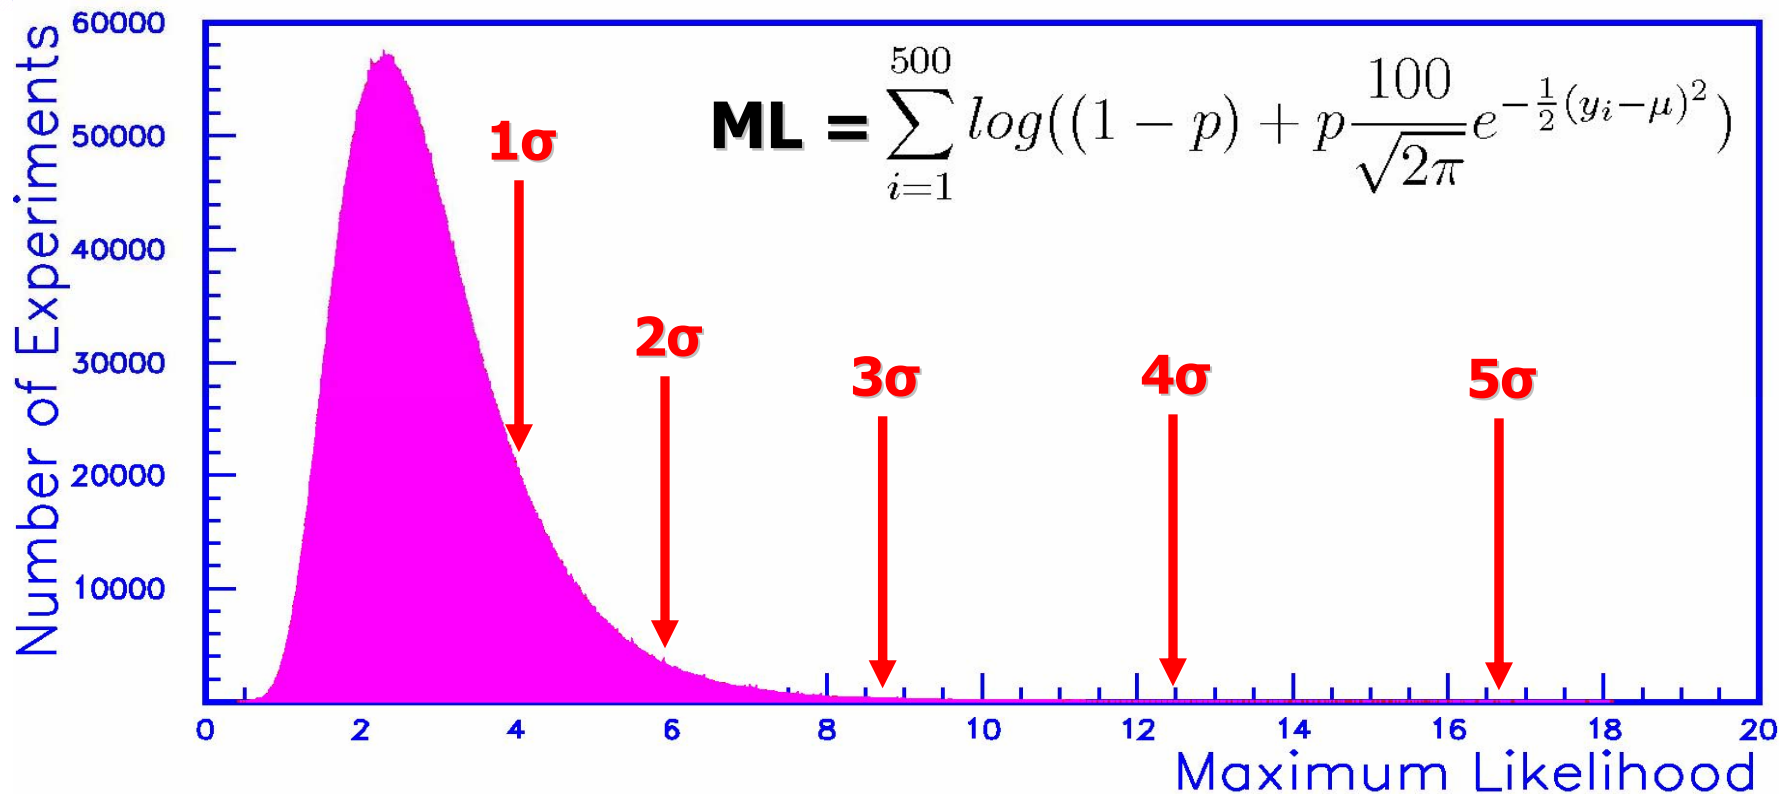

Recalculated significance for SW

S/ \sqrt{B} cutoff values using 13.4 million BKG-only exps

| Step-Size | 1σ | 2σ | 3σ | 4σ | 5σ |
|------------------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|
| 16 | 2.01 | 2.90 | 3.80 | 4.91 | 6.03 |
| 8 | 2.23 | 3.13 | 4.02 | 5.14 | 6.26 |
| 4 | 2.68 | 3.35 | 4.24 | 5.36 | 6.48 |
| 2 | 2.90 | 3.57 | 4.47 | 5.36 | 6.48 |
| 1 | 2.90 | 3.80 | 4.47 | 5.59 | 6.48 |
| 0.5 | 3.13 | 3.80 | 4.69 | 5.81 | 6.93 |
| 0.2 | 3.13 | 4.02 | 4.91 | 5.81 | 6.93 |
| 0.1 | 3.35 | 4.02 | 4.91 | 5.81 | 6.93 |

Recalculated significance for NM

Likelihood cutoff values using 13.4 million BKG-only exps

| NM | 1σ | 2σ | 3σ | 4σ | 5σ |
|-------------------|-------------|-------------|-------------|--------------|--------------|
| Likelihood | 4.00 | 5.94 | 8.71 | 12.48 | 16.61 |

20 signal embedded, 10K exps

$$S/\sqrt{B} \sim 20/\sqrt{20} = 4.47$$

| | 1σ | 2σ | 3σ | 4σ | 5σ |
|------------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|
| 16 | 9834/0 | 8969/0 | 6302/0 | 2215/0 | 356/0 |

Summary/Conclusion

New physics with unknown location or shape:
Significance calculation non-trivial!

- LHC “**Discovery Potential**” over-estimated, depends on specifics of the method (**step-size** and the **situation it applies to, etc**)
- “**Sensitivity**” depends on exact location of signal, and specifics of the method and situation
- **General procedures** for significance calculation and comparison of different search methods
- **A new method** more sensitive to new physics, insensitive to the location of the new physics

ATL-COM-PHYS-2006-009

by I. Koletsou, G. Unal and L. Fayard

Significance in searching $H \rightarrow \gamma\gamma$ bw 110 to 140GeV

BKG fluctuation prob. increased by a factor of 25!

**A real problem to address in ALL searches for
New Physics with unknown location or shape!**

Significance in $H \rightarrow \gamma\gamma$

ATL-COM-PHYS-2006-009 (by G. Unal etc):

- **Background: Born or Box for 10 fb^{-1}**
- **$H \rightarrow \gamma\gamma$ Signal: Gaussian**
- **Method: binned χ^2 fits, also compare with S/\sqrt{B}**
- **" 3σ " BKG fluct. Prob.: 0.13% for fixed Higgs mass**
- **Increased to 3% if mass is bw 110GeV and 140GeV**
- **Can NOT distinguish a " 3σ " signal from a " 3σ " statistical fluctuation of background events**
- **First physics channel to address the significance issue due to unknown location of the signal**

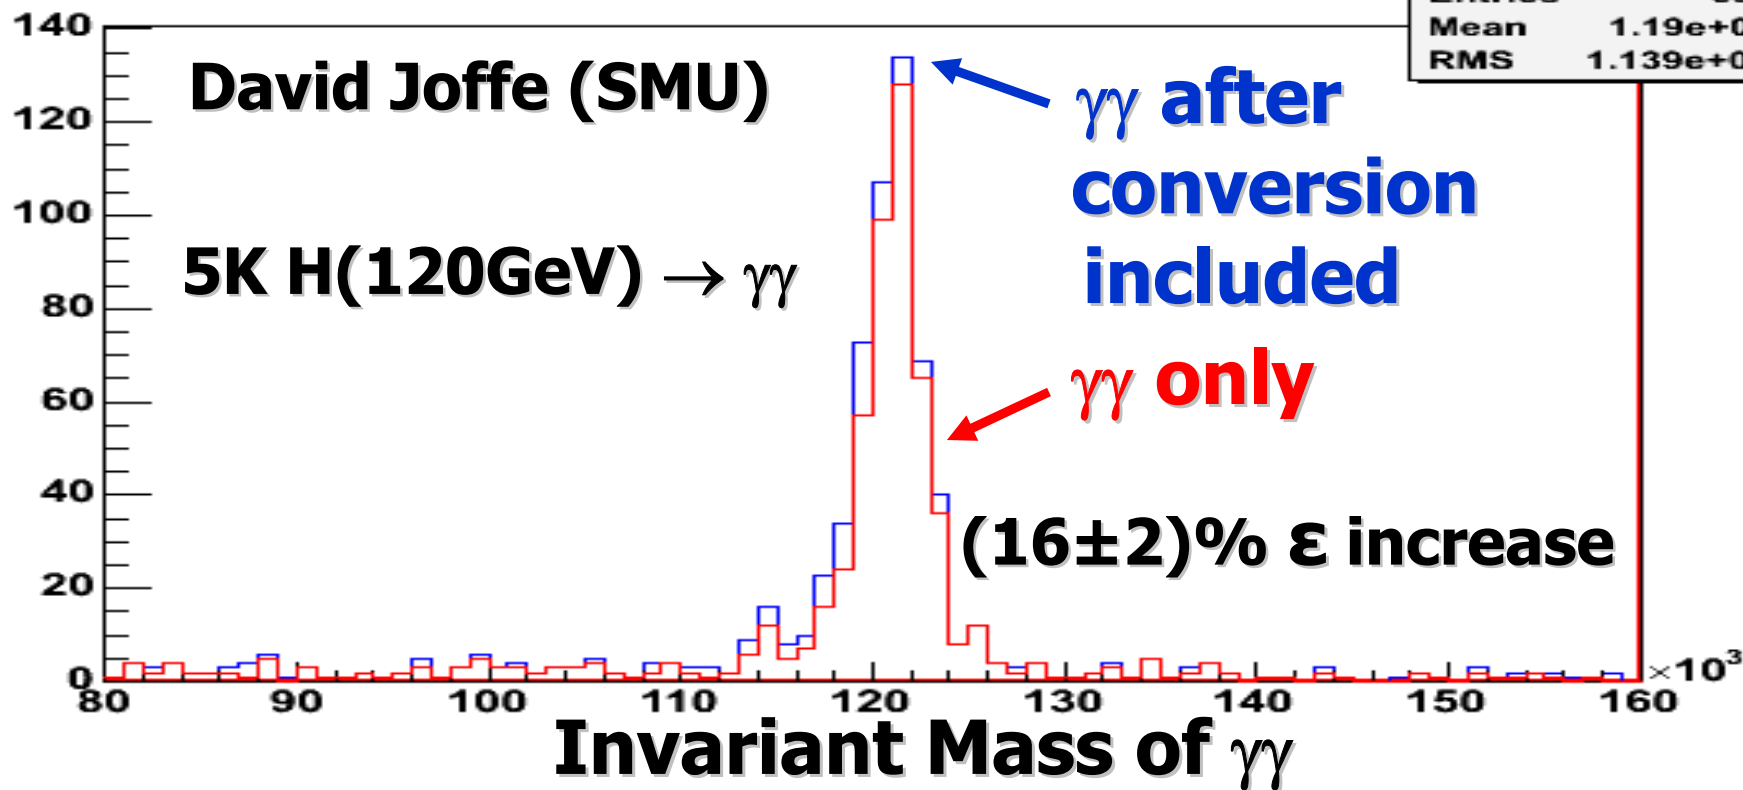

ATLAS/LHC Searches for New Physics:

- **Correctly evaluate the significance of each channel**
- **Maximize discovery potential for each channel**

Photon Conversion & $H \rightarrow \gamma\gamma$
